

Four ways *hearing loss* affects *brain health*

1

Hearing loss leads to social isolation

Untreated hearing loss has long been linked to increased social isolation and loneliness, which studies have shown are well-established risk factors for Alzheimer's and dementia¹.

Growing evidence indicates that older adults with hearing loss are more likely to experience the symptoms of cognitive decline.

Here are three reasons why — plus one thing you can do to help minimize the risk.

2

Hearing loss shifts your cognitive load

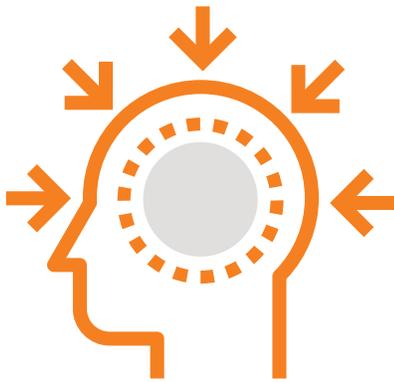

Imagine your brain has a finite amount of fuel. As hearing becomes more difficult, you use more “fuel” to comprehend what you’re listening to — meaning you have less for memory and decision-making. Scientists refer to it as the “cognitive load theory.”

3

Hearing loss accelerates brain shrinkage

Believe it or not — our brains shrink as we age. But MRIs of people with hearing loss show the brain “shrinks” faster than normal, likely due to lack of stimulation².

4

Treating hearing loss can help reduce the risk of cognitive decline and dementia

Two studies — one completed in 2015 and one in 2017 — determined that treating hearing loss (with hearing aids) can reduce the risk of cognitive decline associated with hearing loss³ and can help prevent dementia⁴.

The benefits of wearing hearing aids may also include⁵:

- Reduced mental fatigue
- Decreased feelings of isolation and depression
- Improved ability to do several things at once
- Improved memory, attention and focus
- Improved communication skills
